
Session 1 (2h) — Prompt Fundamentals

Core concepts (1h)

- **A prompt has 4 useful parts** (not all required every time, but worth knowing):
 1. **Task** — what you actually want done
 2. **Context** — the background info the AI needs (your CAD file's dimensions, the error message, the audience for a report)
 3. **Constraints** — format, length, tone, things to avoid
 4. **Examples** — what “good” looks like (covered more in Session 2)
- **Vague vs specific prompts** — “help with my code” gets a generic answer; “this Arduino interrupt handler double-counts button presses, here's the code and the symptom” gets a targeted one. Specificity is the single biggest lever you control.
- **Iteration is normal** — a good prompt is rarely right on the first try. Treat the first response as a draft, and refine your prompt (or ask a follow-up) rather than starting over.
- **Where 생성AI 활용 fits an internship** — it's a force-multiplier for the *boring but necessary* parts of the work (writing docstrings, drafting a status report, explaining an error message) — not a replacement for understanding your own CAD/Arduino/print work.

Hands-on practice (1h)

1. Pick one real problem from another prep pack — e.g. a 3D print defect you're troubleshooting, or an Arduino compile error.
2. Write a **vague** version of the prompt (“my print looks bad, help”) and note the response.
3. Rewrite it with Task + Context + Constraints (“My PLA print of a 40x40x20mm enclosure has stringing between separated features. Layer height 0.2mm, 210°C nozzle. Give me the 3 most likely causes ranked by probability, one line each.”) — compare the two responses.
4. Write down, in your own words, what specifically changed in the second response's quality.

Checkpoint

- ☐ Can name the 4 useful parts of a prompt
- ☐ Wrote and compared a vague vs. specific prompt on a real problem
- ☐ Can explain why iteration (not one perfect prompt) is the normal workflow
